3.2.5 Improvement and Learning Curve Model	8
3.3 Worked Examples	9
Module 2: Cash Flow, Interest, and Equivalence	15
1 Cash Flow, Interest, and Equivalence	15
1.1 Cash Flow Diagrams	15
1.2 Time Value of Money (TVM)	15
1.3 Simple vs. Compound Interest	16
1.4 Nominal and Effective Interest Rates	16
1.5 Economic Equivalence	16
2 Time Value of Money Factors	16
2.1 TVM Factors Summary Table	17
2.2 Debt Repayment (Loan Amortization)	17
3 Cash Flow and Rate of Return Analysis	17
3.1 Present Worth, Future Worth, and Annual Worth Analysis	18
3.2 Internal Rate of Return (IRR) Analysis	18
3.3 Benefit-Cost Ratio (BCR) Analysis	18
3.4 Sensitivity and Breakeven Analysis	18
4 Worked Examples	19

Module 3: Inflation and Price Change	24
1 Inflation and Price Change	24
1.1 Inflation Concepts	24
1.2 Interest Rates under Inflation (Fisher's Equation)	24
1.3 Differential Inflation Rates	24
2 Present Worth Analysis & Mutual Exclusivity	25
2.1 Project Comparison Viewpoints	25
2.2 Effect of Income Taxes	25
2.3 Comparing Projects with Unequal Lives	25
3 Uncertainty in Future Events	25
3.1 Expected Value	25
3.2 Economic Decision Trees	26
4 Worked Examples	26
Module 4: Depreciation Calculations	32
1 Depreciation Calculations	32
1.1 Depreciation Concepts	32
1.2 Straight-Line (SL) Depreciation	32
1.3 Declining Balance (DB) & Double Declining Balance (DDB)	32
2 Replacement Analysis	33
2.1 Economic Service Life (ESL)	33
2.2 Defender vs. Challenger Comparison	33
3 Basic Accounting for Engineers	34
3.1 Financial Statements	34
3.2 Financial Ratios	34
3.3 Cost Accounting and Allocation	35
4 Worked Examples	35

Module 1

Economic Decision Making

1. Economic Decision Making

Engineering Economics: A systematic discipline that applies economic principles, techniques, and methodologies to evaluate engineering alternatives. It translates physical engineering designs into financial metrics to determine their feasibility and profitability.

1.1 Overview and Problems

Engineering problems are solved using two types of criteria:

1. **Physical/Technical Criteria:** Assesses whether an alternative is physically feasible (e.g., strength, efficiency, speed, material availability, safety).
2. **Economic Criteria:** Assesses whether the alternative is financially viable (e.g., capital cost, rate of return, life-cycle cost, return on investment).

The core problem in engineering economics is the **allocation of scarce resources** (capital, labor, materials, and time) among competing engineering proposals to achieve maximum economic efficiency.

1.2 Role of Engineering Economics in Engineering Decisions

An engineer has a dual role: as a designer/technical expert, and as an economic evaluator. The key roles include:

- **Alternative Selection:** Comparing different designs, processes, or equipment to find the most cost-effective solution.
- **Capital Budgeting:** Evaluating whether a project warrants the investment of company funds.
- **Operational Efficiency:** Identifying opportunities to reduce operating, maintenance, and utility costs.
- **Replacement Decisions:** Determining the optimal time to retire old assets and acquire new ones.

1.3 The Decision-Making Process

The economic decision-making process is an iterative, structured sequence of steps:

The Step-by-Step Economic Decision-Making Process

2. Engineering Costs and Estimation

To make sound economic decisions, engineers must understand the different classifications of costs.

2.1 Fixed and Variable Costs

Fixed Costs (FC): Costs that remain constant in total, independent of the level of output or operational activity within a defined range.

Variable Costs (VC): Costs that vary in direct proportion to the volume of output or activity level.

Total Cost Equation

The total cost (TC) for a production volume q is expressed as:

$$TC(q) = FC + VC(q) = FC + (v \times q) \quad (1)$$

Where:

FC = Total Fixed Cost

$VC(q)$ = Total Variable Cost for output q

v = Variable cost per unit of output

q = Quantity produced (output volume)

2.2 Marginal and Average Costs

Marginal Cost (MC): The incremental cost incurred by producing one additional unit of output.

Average Cost (AC): The total cost per unit of output produced.

Average and Marginal Cost Formulas

For a total cost function $TC(q)$:

$$AC(q) = \frac{TC(q)}{q} = \frac{FC}{q} + v \quad (2)$$

$$MC(q) = \frac{d(TC)}{dQ} \quad (\text{continuous}) \quad \text{or} \quad MC = \frac{\Delta TC}{\Delta q} \quad (\text{discrete}) \quad (3)$$

2.3 Sunk Costs and Opportunity Costs

Sunk Cost: A cost that has already been incurred in the past and cannot be recovered by any current or future action. Sunk costs are **irrelevant** for future-oriented decision-making.

Opportunity Cost: The benefit or return forgone (lost) by choosing a specific alternative over the next best alternative. It represents the value of resources in their best alternative use.

Exam Tip: The Sunk Cost Fallacy

A common error in decision-making is trying to justify continuing an investment or project because "we have already spent so much money on it." In engineering economics, past expenditures are gone. Decisions must be based solely on future cash flows, incremental costs, and benefits.

2.4 Recurring and Nonrecurring Costs

- **Recurring Costs:** Expenses that occur repeatedly and predictably at regular intervals during the life cycle of an asset (e.g., annual maintenance, insurance, utility bills, raw material purchases).
- **Nonrecurring Costs:** One-time, non-repetitive expenses that occur at specific points, typically at the beginning or end of a project (e.g., initial research and development, land acquisition, equipment purchasing, installation, decommissioning costs).

2.5 Incremental and Life-Cycle Costs

- **Incremental Cost:** The difference in total cost between two or more feasible alternatives. If Alternative A costs \$12,000 and Alternative B costs \$15,000, the incremental cost of choosing Alternative B over A is \$3,000.
- **Life-Cycle Cost (LCC):** The sum of all costs associated with a product, structure, system, or service over its entire life span. It covers all phases: acquisition, operation, maintenance, and disposal.

2.6 Cash Costs vs. Book Costs

It is critical to distinguish between transactions that involve real money and those that are purely accounting entries.

Parameter	Cash Cost	Book Cost
Definition	Cost that involves an actual cash transaction or out-of-pocket payment.	Cost recorded in accounting books but does not involve a physical cash flow.
Examples	Purchase of raw materials, labor wages, utility bills, rent.	Depreciation of equipment, asset write-downs.
Decision Role	Directly used in economic analysis and cash flow calculations.	Mostly ignored in cash flow analysis (except for their impact on taxes).

3. Cost Estimation Models

Cost estimation is the process of predicting the cost of a future engineering project or product.

3.1 Types of Estimate

Estimates vary in their detail, accuracy, and timing:

- 1. Rough / Order-of-Magnitude Estimate:** Done during the initial conceptual phase. Accuracy is low ($\pm 30\%$). Uses historical data and simple scaling factors.
- 2. Semi-detailed / Budget Estimate:** Prepared during the preliminary design phase when major parameters are defined. Accuracy is moderate ($\pm 15\%$).
- 3. Detailed / Engineer's Estimate:** Prepared during the final design/bidding phase based on complete specifications and bills of materials. Accuracy is high ($\pm 5\%$).

3.2 Estimating Models

3.2.1 Per-Unit Model

A simple model where the total cost is estimated by multiplying the number of units by a historical per-unit cost factor.

$$C = U \times N \quad (4)$$

Where C is the total cost, U is the cost per unit (e.g., cost per square foot of building space, cost per mile of highway), and N is the number of units.

3.2.2 Segmenting Model

Estimates the total cost by dividing the project into individual components or segments, estimating the cost of each segment separately, and summing them.

$$C = \sum_{i=1}^m C_i \quad (5)$$

Where C_i is the cost of segment i , and m is the total number of segments. This is a bottom-up estimation technique.

3.2.3 Cost Index Model

Adjusts historical costs to present or future costs using cost indices that reflect inflation and changing economic conditions over time.

Cost Index Formula

$$C_t = C_0 \times \left(\frac{I_t}{I_0} \right) \quad (6)$$

Where:

C_t = Estimated cost at time t (present/future)

C_0 = Historical cost at reference time 0 (past)

I_t = Cost index value at time t

I_0 = Cost index value at reference time 0

3.2.4 Power-Sizing Model

Used to estimate the cost of industrial equipment, plants, or facilities of different capacities. It accounts for economies of scale.

Power-Sizing Formula

$$C_A = C_B \times \left(\frac{S_A}{S_B} \right)^x \quad (7)$$

Where:

C_A = Estimated cost of equipment/facility A

C_B = Historical cost of equipment/facility B

S_A = Size or capacity of equipment/facility A

S_B = Size or capacity of equipment/facility B

x = Sizing exponent (reflects economies of scale)

The Six-Tenths Rule: If the sizing exponent x is unknown, a default value of $x = 0.6$ is often used (applicable to many chemical process reactors, tanks, and pumps).

$x < 1$: Economies of scale (cost increases slower than capacity).

$x = 1$: Linear scaling (no scale advantage).

$x > 1$: Diseconomies of scale (cost increases faster than capacity).

3.2.5 Improvement and Learning Curve Model

Reflects the phenomenon where the direct labor hours required to perform a repetitive task decrease as the cumulative number of units produced increases.

Crawford's Learning Curve Model

The time or cost to produce the N -th unit, Z_N , is given by:

$$Z_N = K \times N^b \quad (8)$$

Where:

Z_N = Time or cost required to produce the N -th unit

K = Time or cost required to produce the 1st unit

N = Cumulative number of units produced

b = Learning exponent (index of learning)

The learning exponent b is related to the learning rate L (expressed as a decimal, e.g., 0.80 for an 80% curve) by:

$$b = \frac{\log(L)}{\log(2)} = \frac{\ln(L)}{\ln(2)} \quad (9)$$

Every time the cumulative production doubles (e.g., from 1 to 2, 2 to 4, 4 to 8), the time to produce that doubled unit is multiplied by the learning rate L :

$$Z_{2N} = L \times Z_N \quad (10)$$

3.3 Worked Examples**Example 1: Cost Index Model**

Problem: In 2018, a company installed a heat exchanger at a cost of \$85,000. The plant cost index in 2018 was 560. Estimate the cost of installing an identical heat exchanger in 2026, when the cost index is projected to be 840.

Solution: Identify the given parameters:

Reference Cost $C_0 = \$85,000$

Reference Index $I_0 = 560$

Project Index $I_t = 840$

Using the Cost Index formula:

$$C_{2026} = C_0 \times \left(\frac{I_t}{I_0} \right)$$

$$C_{2026} = 85,000 \times \left(\frac{840}{560} \right)$$

$$C_{2026} = 85,000 \times 1.5$$

$$C_{2026} = \$127,500$$

Answer: The estimated cost of the heat exchanger in 2026 is **\$127,500**.

Example 2: Power-Sizing Model

Problem: A water treatment plant with a capacity of 2.5 million gallons per day (MGD) was constructed in 2020 for \$3.2 million. Estimate the cost of a similar plant with a capacity of 6.0 MGD if the power-sizing exponent is $x = 0.68$.

Solution: Identify the given parameters:

Reference capacity $S_B = 2.5$ MGD, Reference cost $C_B = \$3,200,000$

Target capacity $S_A = 6.0$ MGD

Sizing exponent $x = 0.68$

Using the Power-Sizing formula:

$$C_A = C_B \times \left(\frac{S_A}{S_B} \right)^x$$

$$C_A = 3,200,000 \times \left(\frac{6.0}{2.5} \right)^{0.68}$$

$$C_A = 3,200,000 \times (2.4)^{0.68}$$

Calculate the capacity ratio term:

$$(2.4)^{0.68} \approx 1.8155$$

$$C_A \approx 3,200,000 \times 1.8155$$

$$C_A \approx \$5,809,600$$

Answer: The estimated cost of the 6.0 MGD plant is **\$5,809,600**.

Example 3: Learning Curve Model

Problem: The first prototype of a satellite communications receiver requires 80 direct labor hours to assemble. The manufacturing line has an estimated learning rate of 85%.

a. Calculate the learning exponent b .

b. Estimate the labor hours required to assemble the 8th unit.

Solution: (a) **Calculate the learning exponent b :** Using the formula $b = \frac{\log(L)}{\log(2)}$ with $L = 0.85$:

$$b = \frac{\log(0.85)}{\log(2)} \approx \frac{-0.07058}{0.30103} \approx -0.2345$$

(b) **Estimate labor hours for the 8th unit ($N = 8$):** *Method 1: Direct Formula*

$$Z_8 = K \times 8^b$$

$$Z_8 = 80 \times 8^{-0.2345}$$

$$Z_8 \approx 80 \times 0.6141 \approx 49.13 \text{ hours}$$

Method 2: Doubling Principle (Verification) Since 8 is a double of 4, which is a double of

2, which is a double of 1:

$$Z_1 = 80 \text{ hours}$$

$$Z_2 = 80 \times 0.85 = 68 \text{ hours}$$

$$Z_4 = 68 \times 0.85 = 57.8 \text{ hours}$$

$$Z_8 = 57.8 \times 0.85 = 49.13 \text{ hours}$$

Both methods yield identical results.

Answer: (a) The learning exponent b is **-0.2345**. (b) The labor hours for the 8th unit is **49.13 hours**.

Quick Revision — Module I

Introduction & Cost Estimation | HS-HU601

Key Formulas at a Glance

Total Cost	$TC(q) = FC + VC = FC + (v \times q)$
Average Cost	$AC(q) = \frac{TC(q)}{q} = \frac{FC}{q} + v$
Marginal Cost	$MC(q) = \frac{d(TC)}{dq} \approx \frac{\Delta TC}{\Delta q}$
Cost Indexing	$C_t = C_0 \times \left(\frac{I_t}{I_0}\right)$
Power-Sizing	$C_A = C_B \times \left(\frac{S_A}{S_B}\right)^x$ (six-tenths rule: $x = 0.6$)
Learning Curve	$Z_N = K \times N^b$
Learning Exponent	$b = \frac{\log(L)}{\log(2)}$ (L = learning rate as a decimal)

One-Line Definitions

- **Fixed Cost:** Expense that does not change with production output (e.g., rent, insurance).
- **Variable Cost:** Expense that increases or decreases proportionally with output volume (e.g., raw materials).
- **Sunk Cost:** Past expense that cannot be recovered; irrelevant for future decision-making.
- **Opportunity Cost:** The potential benefit lost by choosing one alternative over another.
- **Incremental Cost:** The change in total cost resulting from selecting one alternative over another.
- **Cash Cost:** Cost representing an out-of-pocket transaction involving actual cash flow.
- **Book Cost:** Recorded non-cash expense representing accounting transactions (e.g., depreciation).
- **Life-Cycle Cost:** The sum of all costs (acquisition, O&M, disposal) over the lifespan of an asset.

Frequently Asked / Viva Questions

Q1. What is the difference between physical and economic feasibility?

Physical feasibility ensures an engineering design is mechanically and structurally possible, while economic feasibility ensures it makes financial sense and yields a positive return.

Q2. Why are sunk costs completely ignored in economic decision-making?

Sunk costs are historical expenditures that cannot be changed by any present or future choice. Only future incremental cash flows are affected by new decisions.

Q3. Explain opportunity cost with a practical engineering example.

Opportunity cost is the profit forgone from an unselected alternative. For example, if a firm uses its warehouse for assembly rather than renting it out for \$5,000/month, the opportunity cost of assembly is \$5,000/month.

Q4. What is the "six-tenths rule" in cost estimation?

The six-tenths rule is an empirical rule stating that the cost of a new facility/equipment of size S_A is estimated as the cost of reference size S_B multiplied by $(S_A/S_B)^{0.6}$.

Q5. What is the difference between cash costs and book costs in engineering accounts?

Cash costs require an actual cash outflow (e.g., wages, raw materials). Book costs are accounting entries that do not involve cash flows (e.g., depreciation).

Q6. How does the Crawford learning curve model function?

It states that the time to produce the N -th unit decreases exponentially according to $Z_N = K \times N^b$. Every time cumulative production doubles, unit labor time decreases by the learning rate.

Q7. What does a power-sizing exponent $x < 1.0$ indicate?

It indicates economies of scale, meaning that doubling the capacity of the equipment will result in a cost increase of less than double ($2^x < 2$).

Q8. Why is life-cycle cost (LCC) a better decision metric than initial acquisition cost?

An alternative with a lower purchase price may have high operating and maintenance costs. LCC accounts for all costs from acquisition to disposal, preventing long-term deficits.

Q9. Distinguish between recurring and nonrecurring costs.

Recurring costs are periodic and repetitive (e.g., annual maintenance, monthly utility bills). Nonrecurring costs are one-time costs (e.g., land purchase, design costs).

Q10. What are the typical accuracy ranges for the three major types of cost estimates?

Rough/Order-of-Magnitude estimate has an accuracy of $\pm 30\%$; Semi-detailed/Budget has $\pm 15\%$; and Detailed/Engineer's estimate has $\pm 5\%$.

Frequently Asked / Viva Questions (contd.)

Q11. What is the sunk cost fallacy, and why is it dangerous in engineering projects?

It is the psychological tendency to continue investing in a failing project because of past non-recoverable expenditures, which leads to further losses.

Q12. What are the components of the total cost equation, and how are average and marginal costs derived?

Total cost is $TC = FC + v \times q$. Average cost is derived by dividing total cost by quantity ($AC = FC/q + v$). Marginal cost is the derivative of total cost with respect to quantity ($MC = v$ for linear costs).

Comparison of Cost Estimating Models

Model Name	Core Formula	Data Needed	Primary Application
Per-Unit	$C = U \times N$	Historical unit rate U , quantity N	Very early stage construction cost (e.g., cost per sq. ft.).
Segmenting	$C = \sum C_i$	Detailed component cost breakdown	Detailed bottom-up estimates; bill of materials.
Cost Index	$C_t = C_0 \left(\frac{I_t}{I_0} \right)$	Historical cost C_0 , historical & current indices	Adjusting past costs for inflation or price changes over time.
Power-Sizing	$C_A = C_B \left(\frac{S_A}{S_B} \right)^x$	Size S , reference cost C_B , exponent x	Estimating industrial equipment/plant capacity cost scaling.
Learning Curve	$Z_N = K \times N^b$	First unit hours K , learning rate L	Estimating labor costs for manufacturing assembly runs.

Module 2

Cash Flow, Interest, and Equivalence

1. Cash Flow, Interest, and Equivalence

To evaluate engineering designs financially, we must track when money is spent and received.

1.1 Cash Flow Diagrams

A Cash Flow Diagram (CFD) is a graphical representation of cash flows plotted on a timeline.

Cash Inflow (Receipts): Represented by vertical arrows pointing **upward** above the timeline (e.g., revenue, operating savings, salvage value).

Cash Outflow (Disbursements): Represented by vertical arrows pointing **downward** below the timeline (e.g., capital purchase, operating expenses, taxes).

Typical Cash Flow Diagram for an Engineering Project

1.2 Time Value of Money (TVM)

The **Time Value of Money** states that a dollar received today is worth more than a dollar received in the future. This is due to three factors: 1. **Opportunity Cost (Interest):** Capital can be invested to earn interest over time. 2. **Inflation:** The purchasing power of money decreases over time. 3. **Risk/Uncertainty:** Future receipts carry the risk of not being realized.

1.3 Simple vs. Compound Interest

- **Simple Interest:** Calculated *only* on the original principal amount.

$$I = P \times i \times n \quad (11)$$

- **Compound Interest:** Interest is calculated on the principal *plus* any accumulated interest from previous periods.

$$F = P \times (1 + i)^n \quad (12)$$

1.4 Nominal and Effective Interest Rates

- **Nominal Interest Rate (r):** The stated annual interest rate without considering compounding frequency within the year.
- **Effective Interest Rate (i_a):** The actual annual rate of interest paid or earned, accounting for compounding m times per year.

Effective Interest Rate Formulas

For a nominal rate r compounded m times per year:

$$i_a = \left(1 + \frac{r}{m}\right)^m - 1 \quad (13)$$

For continuous compounding ($m \rightarrow \infty$):

$$i_a = e^r - 1 \quad (14)$$

1.5 Economic Equivalence

Two cash flows (or series of cash flows) are **economically equivalent** at a given interest rate i if they have the same financial value when discounted to the same point in time.

2. Time Value of Money Factors

To simplify calculations, standardized discount factors are used to convert cash flows between the Present (P), Future (F), and Uniform Series (A).

2.1 TVM Factors Summary Table

Find / Given	Factor Name	Standard Notation	Mathematical Formula
Find F given P	Single Payment Compound Amount	$(F/P, i, n)$	$(1 + i)^n$
Find P given F	Single Payment Present Worth	$(P/F, i, n)$	$(1 + i)^{-n}$
Find F given A	Uniform Series Compound Amount	$(F/A, i, n)$	$\frac{(1 + i)^n - 1}{i}$
Find A given F	Sinking Fund	$(A/F, i, n)$	$\frac{i}{(1 + i)^n - 1}$
Find A given P	Capital Recovery	$(A/P, i, n)$	$\frac{i(1 + i)^n}{(1 + i)^n - 1}$
Find P given A	Uniform Series Present Worth	$(P/A, i, n)$	$\frac{(1 + i)^n - 1}{i(1 + i)^n}$

2.2 Debt Repayment (Loan Amortization)

Amortization is the process of paying off debt through a series of equal periodic payments. Each payment A consists of two parts: 1. **Interest Portion (I_t)**: Computed on the outstanding loan balance at the beginning of period t . 2. **Principal Portion (P_t)**: The remaining part of the payment that reduces the outstanding loan balance.

Loan Amortization Equations

For a loan principal P at interest rate i repaid over n periods:

$$\text{Equal annual payment: } A = P \times (A/P, i, n) = P \times \frac{i(1 + i)^n}{(1 + i)^n - 1} \quad (15)$$

$$\text{Interest in period } t : I_t = B_{t-1} \times i \quad (B_{t-1} \text{ is outstanding balance}) \quad (16)$$

$$\text{Principal reduction in } t : P_t = A - I_t \quad (17)$$

$$\text{Remaining balance after } t : B_t = B_{t-1} - P_t \quad (18)$$

3. Cash Flow and Rate of Return Analysis

Engineers use standard analysis methods to determine if a project is financially viable.

3.1 Present Worth, Future Worth, and Annual Worth Analysis

- **Present Worth (PW) Analysis:** All cash inflows and outflows are discounted to the present ($t = 0$) at the Minimum Attractive Rate of Return (MARR).

$$PW(i) = \sum_{t=0}^n CF_t \times (1+i)^{-t} \quad (19)$$

Decision Rule: Accept the project if $PW(MARR) \geq 0$.

- **Future Worth (FW) Analysis:** Cash flows are compounded to a future point ($t = n$). Useful for determining net accumulation at the end of project life.
- **Annual Worth (AW) Analysis:** Cash flows are converted into an equivalent uniform series over the project life.

$$AW(i) = PW(i) \times (A/P, i, n) \quad (20)$$

Decision Rule: Accept the project if $AW(MARR) \geq 0$.

3.2 Internal Rate of Return (IRR) Analysis

The **Internal Rate of Return (IRR)** is the interest rate at which the Present Worth of all cash flows equals zero.

IRR Equation

$$PW(IRR) = \sum_{t=0}^n \frac{CF_t}{(1+IRR)^t} = 0 \quad (21)$$

**Decision Rule:* Accept the project if $IRR \geq MARR$.

Linear Interpolation formula: If trial rates i_1 (giving $PW_1 > 0$) and i_2 (giving $PW_2 < 0$) are close:

$$IRR \approx i_1 + \left(\frac{PW_1}{PW_1 - PW_2} \right) \times (i_2 - i_1) \quad (22)$$

3.3 Benefit-Cost Ratio (BCR) Analysis

Often used in public sector projects to assess whether the societal benefits justify the public expenditure.

Benefit-Cost Ratio Formula

$$BCR = \frac{PV(\text{Benefits})}{PV(\text{Costs})} = \frac{PW(\text{Cash Inflows})}{PW(\text{Cash Outflows})} \quad (23)$$

**Decision Rule:* Accept the project if $BCR \geq 1.0$.

3.4 Sensitivity and Breakeven Analysis

- **Sensitivity Analysis:** Determines how financial metrics (like PW or IRR) change when key parameters (like initial cost, useful life, or annual revenue) deviate from their estimated values.

- **Breakeven Analysis:** Determines the value of a parameter (e.g., production capacity, price, number of years) at which two alternatives become economically equivalent. At the breakeven point:

$$PW_A(i) = PW_B(i) \quad \text{or} \quad AW_A(i) = AW_B(i) \quad (24)$$

4. Worked Examples

Example 1: Nominal vs. Effective Interest

Problem: An engineering company deposits \$10,000 in a bank account that pays a nominal interest rate of 12% per year. Calculate the effective annual interest rate and the total balance after 5 years under:

- Quarterly compounding ($m = 4$).
- Continuous compounding.

Solution:

(a) Quarterly Compounding ($m = 4$):

$$i_a = \left(1 + \frac{r}{m}\right)^m - 1 = \left(1 + \frac{0.12}{4}\right)^4 - 1 = (1.03)^4 - 1$$

$$i_a \approx 1.1255 - 1 = 12.55\%$$

Future Balance after 5 years ($n = 5 \times 4 = 20$ quarters, interest rate per quarter = 3%):

$$F = P(1 + i)^{n_{quarters}} = 10,000 \times (1.03)^{20}$$

$$F \approx 10,000 \times 1.8061 = \$18,061$$

(b) Continuous Compounding:

$$i_a = e^r - 1 = e^{0.12} - 1 \approx 1.1275 - 1 = 12.75\%$$

Future Balance after 5 years:

$$F = P \times e^{r \times t} = 10,000 \times e^{0.12 \times 5} = 10,000 \times e^{0.60}$$

$$F \approx 10,000 \times 1.8221 = \$18,221$$

Answer: (a) Effective rate = **12.55%**, Balance = **\$18,061**. (b) Effective rate = **12.75%**, Balance = **\$18,221**.

Example 2: Loan Amortization Schedule

Problem: A manufacturing startup borrows \$50,000 to buy CNC tooling. The loan is to be repaid in 5 equal annual installments at a compound interest rate of 8% per year. Calculate the annual payment and find the interest and principal components for Year 1.

Solution: Identify given parameters: Principal $P = \$50,000$, Rate $i = 0.08$, Periods $n =$

5. Calculate the equal annual payment A using Capital Recovery factor ($A/P, 8\%, 5$):

$$A = P \times \frac{i(1+i)^n}{(1+i)^n - 1} = 50,000 \times \frac{0.08(1.08)^5}{(1.08)^5 - 1}$$

$$A = 50,000 \times \frac{0.08 \times 1.4693}{1.4693 - 1} = 50,000 \times 0.25046 = \$12,523$$

Calculate components for **Year 1**:

$$\text{Initial balance } B_0 = \$50,000$$

$$\text{Interest portion } I_1 = B_0 \times i = 50,000 \times 0.08 = \$4,000$$

$$\text{Principal portion } P_1 = A - I_1 = 12,523 - 4,000 = \$8,523$$

$$\text{Ending balance } B_1 = B_0 - P_1 = 50,000 - 8,523 = \$41,477$$

Answer: The equal annual payment is **\$12,523**. In Year 1, the Interest paid is **\$4,000** and the Principal reduction is **\$8,523**.

Example 3: Internal Rate of Return (IRR)

Problem: An energy efficiency project requires an initial outlay of \$25,000 and generates net annual savings of \$6,500 for 5 years. Find the IRR of this project using linear interpolation.

Solution: The cash flows are: $CF_0 = -\$25,000$, $CF_{1..5} = +\$6,500$ (Annuity). We need to find i such that $PW(i) = 0$:

$$PW(i) = -25,000 + 6,500 \times (P/A, i, 5) = 0 \Rightarrow (P/A, i, 5) = \frac{25,000}{6,500} \approx 3.8462$$

Let's try trial interest rates: 1. **Try** $i_1 = 9\%$:

$$(P/A, 9\%, 5) = \frac{(1.09)^5 - 1}{0.09(1.09)^5} \approx 3.8897$$

$$PW(9\%) = -25,000 + 6,500 \times 3.8897 = -25,000 + 25,283 = +\$283 \quad (\text{above zero})$$

2. **Try** $i_2 = 10\%$:

$$(P/A, 10\%, 5) = \frac{(1.10)^5 - 1}{0.10(1.10)^5} \approx 3.7908$$

$$PW(10\%) = -25,000 + 6,500 \times 3.7908 = -25,000 + 24,640 = -\$360 \quad (\text{below zero})$$

Using linear interpolation between $i_1 = 9\%$ and $i_2 = 10\%$:

$$IRR \approx i_1 + \left(\frac{PW(i_1)}{PW(i_1) - PW(i_2)} \right) \times (i_2 - i_1)$$

$$IRR \approx 0.09 + \left(\frac{283}{283 - (-360)} \right) \times (0.10 - 0.09)$$

$$IRR \approx 0.09 + \left(\frac{283}{643} \right) \times 0.01 \approx 0.09 + 0.44 \times 0.01 = 9.44\%$$

Answer: The estimated Internal Rate of Return (IRR) is **9.44%**.

Quick Revision — Module II

Interest & Rate of Return | HS-HU601

Key Formulas at a Glance

Effective Interest	$i_a = (1 + r/m)^m - 1$ (Continuous compounding: $i_a = e^r - 1$)
Single payment PW	$P = F \times (1 + i)^{-n}$
Capital Recovery	$A = P \times \frac{i(1 + i)^n}{(1 + i)^n - 1}$
Uniform series PW	$P = A \times \frac{(1 + i)^n - 1}{i(1 + i)^n}$
IRR Interpolation	$IRR \approx i_1 + \frac{PW_1}{PW_1 - PW_2} \times (i_2 - i_1)$
Benefit-Cost Ratio	$BCR = \frac{PV(\text{Benefits})}{PV(\text{Costs})} = \frac{PW(\text{Inflows})}{PW(\text{Outflows})}$

One-Line Definitions

- **Cash Flow Diagram:** Graphic representation of cash receipts (up) and disbursements (down) over time.
- **Nominal Interest Rate:** Stated annual interest rate without considering sub-year compounding.
- **Effective Interest Rate:** The actual annual rate of interest paid, accounting for compounding periods.
- **Amortization:** Paying off debt in equal installments, consisting of both principal and interest.
- **Present Worth (PW):** The value of future net cash flows discounted to the present at the MARR.
- **Annual Worth (AW):** Equivalent annual uniform series of a project's cash flows over its lifetime.
- **Internal Rate of Return:** The discount rate that makes the Present Worth of all cash flows equal zero.
- **Benefit-Cost Ratio:** Ratio of present worth of benefits to present worth of costs (must be ≥ 1.0).
- **Breakeven Point:** The value of a parameter at which two investment alternatives are economically equivalent.

Frequently Asked / Viva Questions

Q1. What is economic equivalence?

Two different cash flow streams are equivalent at a specific interest rate if they

have the same financial value when discounted to the same point in time.

Q2. What is the difference between nominal and effective interest rates?

Nominal rate is the annual rate ignoring sub-year compounding frequency. Effective rate represents the actual annual interest earned, accounting for compounding within the year.

Q3. How does the principal and interest portion change in loan amortization?

Over time, as the outstanding principal balance decreases, the interest portion of the fixed payment decreases, while the principal repayment portion increases.

Q4. Define the Sinking Fund factor ($A/F, i, n$).

It determines the uniform annual payment (A) needed to accumulate a specific future sum (F) after n years at interest rate i .

Q5. State the decision criteria for Present Worth and Annual Worth analysis.

A project is economically viable if its Present Worth (PW) or Annual Worth (AW), evaluated at the MARR, is greater than or equal to zero (≥ 0).

Q6. What is the Minimum Attractive Rate of Return (MARR)?

The minimum interest rate a company requires on its capital investments before accepting a project, based on its cost of capital and risk.

Q7. How is the Internal Rate of Return (IRR) calculated?

By setting the $PW(i) = 0$ and solving for i . In practice, it is solved by finding two rates where PW changes sign and interpolating linearly between them.

Q8. Why is continuous compounding relevant in engineering economics?

It represents the limit as compounding frequency approaches infinity. It is used in advanced financial modeling and for automated, continuous transactions.

Q9. Explain the Benefit-Cost Ratio decision rule.

If $BCR \geq 1.0$, the discounted benefits exceed the discounted costs, meaning the project is acceptable. If $BCR < 1.0$, the project is rejected.

Q10. What is the purpose of sensitivity analysis in engineering designs?

It assesses how variations or uncertainty in estimated parameters (e.g., initial cost, salvage value, inflation) affect the project's profitability.

Frequently Asked / Viva Questions (contd.)

Q11. Define the Capital Recovery factor $(A/P, i, n)$ and explain its economic meaning.

It represents the equivalent annual cost of owning an asset, combining both the initial purchase depreciation and the interest cost on the invested capital.

Q12. What occurs at the breakeven point between two engineering alternatives?

The two alternatives become economically equivalent, meaning their present worths or annual worths are identical. Choosing either alternative yields the same economic result.

Comparison of TVM Factors and Operations

Factor Symbol	Name	Core Formula	Typical Application
$(F/P, i, n)$	Compound Amount	$(1 + i)^n$	Finding the future value of a single deposit.
$(P/F, i, n)$	Present Worth	$(1 + i)^{-n}$	Discounting a single future payment back to present.
$(F/A, i, n)$	Uniform Compound	$\frac{(1 + i)^n - 1}{i}$	Accumulating a pension fund through yearly deposits.
$(A/P, i, n)$	Capital Recovery	$\frac{i(1 + i)^n}{(1 + i)^n - 1}$	Determining equal annual mortgage or loan payments.
$(P/A, i, n)$	Uniform Present	$\frac{(1 + i)^n - 1}{i(1 + i)^n}$	Evaluating the present worth of uniform annual savings.

Module 3

Inflation and Price Change

1. Inflation and Price Change

Financial plans made in a stable environment can fail when prices rise over time.

1.1 Inflation Concepts

Inflation: A general and progressive increase in the prices of goods and services over time, resulting in a decline in the purchasing power of money.

Consumer Price Index (CPI): A measure that examines the weighted average of prices of a basket of consumer goods and services. It is used to estimate price changes.

1.2 Interest Rates under Inflation (Fisher's Equation)

Inflation separates the interest rate earned into a **nominal (market) rate** and a **real rate**.

- **Nominal Interest Rate (i):** The actual interest rate paid or earned in the market.
- **Real Interest Rate (i'):** The interest rate adjusted to represent the real increase in purchasing power.
- **Inflation Rate (f):** The rate at which the price index increases.

Fisher's Equation

The relationship between nominal interest, real interest, and inflation is:

$$1 + i = (1 + i') \times (1 + f) \quad (25)$$

Expanding this gives:

$$i = i' + f + (i' \times f) \quad (26)$$

To find the real interest rate:

$$i' = \frac{i - f}{1 + f} \quad (27)$$

1.3 Differential Inflation Rates

Different components of a project (e.g., fuel, labor, equipment) may inflate at different rates. If a specific cost inflates at rate f_j , its future cash flow in year t is:

$$CF_t = CF_0 \times (1 + f_j)^t \quad (28)$$

This is then discounted back to present using the market interest rate i .

2. Present Worth Analysis & Mutual Exclusivity

When comparing competing engineering projects, specific conventions must be followed.

2.1 Project Comparison Viewpoints

1. **Economic Studies Viewpoint:** Assesses the project based on total investment capital, ignoring how the project is financed. 2. **Borrowed Money Viewpoint:** Includes the cash flows of borrowing (receipt of loan principal) and debt repayment (interest and principal payments).

2.2 Effect of Income Taxes

Corporate income taxes reduce net cash inflows.

- Taxable Income = Revenues – Operating Expenses – Depreciation
- Income Tax = Taxable Income $\times$ Corporate Tax Rate (t)
- **Tax Depreciation Shield:** Depreciation is a non-cash expense that reduces taxable income, shielding the company from taxes. The annual tax savings equal:

$$\text{Tax Shield} = t \times d_t \quad (d_t \text{ is the depreciation in year } t) \quad (29)$$

2.3 Comparing Projects with Unequal Lives

We cannot compare the Present Worth of two alternatives directly if they have different useful lives because the service periods differ.

- **Least Common Multiple (LCM) Method:** Compare projects over a study period equal to the LCM of their lives. It assumes that each alternative will be replaced at the end of its life with an identical asset at the same cost.
- **Co-termination (Study Period) Method:** A fixed study period is selected (e.g., 5 years). Any alternative with a shorter life is replaced, and any alternative with a longer life is assigned a salvage value at the end of the study period.

3. Uncertainty in Future Events

Engineering estimates of future costs and revenues are rarely certain.

3.1 Expected Value

When future cash flows are uncertain but can be assigned probabilities:

Expected Value Formula

The expected value ($E[X]$) of a random cash flow variable X is:

$$E[X] = \sum_{j=1}^M x_j \times P(x_j) \quad (30)$$

Where x_j is the cash flow under outcome j , $P(x_j)$ is its probability, and M is the number of outcomes.

3.2 Economic Decision Trees

A decision tree is a graphical tool used to analyze decisions under risk.

- **Decision Nodes (Squares):** Points where the decision-maker must select an alternative.
- **Chance Nodes (Circles):** Points where outcomes are determined by probability.
- **Branches:** Connect nodes; chance branches show probabilities and outcomes.

Economic Decision Tree for Plant Expansion

4. Worked Examples

Example 1: Fisher's Equation

Problem: An electronics engineer wants to earn a real rate of return of 6% per year on an investment. If inflation is projected to run at an average rate of 4% per year over the next few years, what nominal market interest rate must the investment yield?

Solution: Identify given parameters: Real interest rate $i' = 0.06$, Inflation rate $f = 0.04$. Using Fisher's Equation:

$$\begin{aligned} i &= i' + f + (i' \times f) \\ i &= 0.06 + 0.04 + (0.06 \times 0.04) \\ i &= 0.10 + 0.0024 \\ i &= 0.1024 = 10.24\% \end{aligned}$$

Alternative check using $(1 + i)$:

$$1 + i = (1 + i')(1 + f) = (1.06) \times (1.04) = 1.1024 \quad \Rightarrow \quad i = 10.24\%$$

Answer: The investment must yield a nominal market interest rate of **10.24%**.

Example 2: Mutually Exclusive Projects with Unequal Lives

Problem: Compare two manufacturing machines at an interest rate of 10% using the Present Worth method.

- **Machine A:** Initial cost = \$10,000, useful life = 2 years, annual operating cost = \$2,000.
- **Machine B:** Initial cost = \$15,000, useful life = 3 years, annual operating cost = \$1,500.

Solution: The lives are unequal (2 and 3 years). The study period must be the Least Common Multiple:

$$\text{Study Period} = \text{LCM}(2, 3) = 6 \text{ years}$$

- **Machine A (re-purchased at end of Year 2 and Year 4):**

Cash outflows occur at $t = 0$ (\$10k), $t = 2$ (\$10k), $t = 4$ (\$10k), and annual costs of \$2k for Years 1..6.

$$PW_A(10\%) = -10,000 - 10,000 \times (P/F, 10\%, 2) - 10,000 \times (P/F, 10\%, 4) - 2,000 \times (P/A, 10\%, 6)$$

$$PW_A(10\%) = -10,000 - 10,000(0.8264) - 10,000(0.6830) - 2,000(4.3553)$$

$$PW_A(10\%) = -10,000 - 8,264 - 6,830 - 8,711 = -\$33,805$$

- **Machine B (re-purchased at end of Year 3):**

Cash outflows occur at $t = 0$ (\$15k), $t = 3$ (\$15k), and annual costs of \$1.5k for Years 1..6.

$$PW_B(10\%) = -15,000 - 15,000 \times (P/F, 10\%, 3) - 1,500 \times (P/A, 10\%, 6)$$

$$PW_B(10\%) = -15,000 - 15,000(0.7513) - 1,500(4.3553)$$

$$PW_B(10\%) = -15,000 - 11,270 - 6,533 = -\$32,803$$

Comparing the Present Worths over 6 years:

$$PW_B(-\$32,803) > PW_A(-\$33,805) \quad (\text{Machine B has lower net present cost})$$

Answer: Machine B is selected since it minimizes the net present cost over the 6-year study period.

Example 3: Decision Tree Rollback

Problem: Roll back the plant expansion decision tree shown in Section 3.2. Find the expected value for each alternative and determine the optimal decision.

Solution: Calculate the Expected Value (EV) for each decision branch: 1. **Branch 1: Expand** The outcomes are High Demand (+\$100k at $P = 0.6$) and Low Demand (−\$20k at $P = 0.4$).

$$\begin{aligned} EV(\text{Expand}) &= 100,000 \times 0.6 + (-20,000) \times 0.4 \\ &= 60,000 - 8,000 = \$52,000 \end{aligned}$$

2. Branch 2: Do Nothing The outcomes are High Demand (+\$30k at $P = 0.6$) and Low Demand (+\$10k at $P = 0.4$).

$$\begin{aligned}EV(\text{Do Nothing}) &= 30,000 \times 0.6 + 10,000 \times 0.4 \\&= 18,000 + 4,000 = \$22,000\end{aligned}$$

Compare expected values at the root decision node:

$$EV(\text{Expand}) = \$52,000 > EV(\text{Do Nothing}) = \$22,000$$

The optimal choice is to select the path with the highest expected value.

Answer: The optimal decision is to **Expand**, with an expected value of **\$52,000**.

Quick Revision — Module III

Inflation, Present Worth & Uncertainty | HS-HU601

Key Formulas at a Glance

Fisher's Equation	$i = i' + f + i'f$
Real Interest Rate	$i' = \frac{i - f}{1 + f}$
Tax Depreciation Shield	Tax Savings = $t \times d_t$ (t = tax rate, d_t = depreciation)
Expected Value	$E[X] = \sum x_j P(x_j)$
LCM Study Period	Study Period = Least Common Multiple of individual project lives

One-Line Definitions

- **CPI:** An index measuring inflation by tracking average price changes of consumer goods.
- **Real Interest Rate:** The rate of return adjusted to reflect actual increases in purchasing power.
- **Tax Shield:** The reduction in income tax liability resulting from tax-deductible depreciation.
- **LCM Method:** Project comparison method over a study period matching the least common multiple of their lives.
- **Co-termination:** Comparing alternatives over a fixed study period, assigning salvage value to remaining assets.
- **Expected Value:** Weighted average of all possible numerical outcomes, using probabilities as weights.
- **Decision Tree:** Graphical model displaying sequential decisions, probabilities, and financial outcomes.
- **Monte Carlo Simulation:** Computational algorithm that uses repeated random sampling to model uncertainty.

Frequently Asked / Viva Questions

Q1. How does inflation affect the value of cash flows over time?

Inflation reduces the purchasing power of money, meaning future cash flows are worth less in real terms than nominal terms.

Q2. State Fisher's Equation and define its variables.

$i = i' + f + i'f$, where i is the nominal market interest rate, i' is the real interest

rate, and f is the inflation rate.

Q3. What is the difference between the economic studies and borrowed money viewpoints?

Economic studies viewpoint evaluates a project based on total capital requirements, ignoring financing. Borrowed money viewpoint includes the loan receipts and debt payments.

Q4. How does depreciation act as a tax shield?

Depreciation is a non-cash expense that is subtracted from revenue to calculate taxable income. By lowering taxable income, it reduces corporate tax liability.

Q5. Why can we not compare PW of unequal-life alternatives directly?

Because the alternatives do not provide service over the same timeframe. Comparing them directly over different lives violates the equal-service comparison rule.

Q6. Describe the assumption behind the Least Common Multiple (LCM) method.

It assumes that each alternative can be replaced at the end of its life with an identical asset having the same initial cost and operating costs.

Q7. Explain the co-termination method for comparing unequal-life projects.

A specific study period is chosen. Shorter-lived alternatives are replaced, and longer-lived alternatives are terminated early, assigning them a salvage value.

Q8. What is the difference between decision nodes and chance nodes in a decision tree?

Decision nodes (squares) represent points where the engineer has control over choices. Chance nodes (circles) represent points where outcomes occur based on probability.

Q9. How do we roll back (solve) a decision tree?

We work from right to left (backwards). At each chance node, we calculate the expected value. At each decision node, we select the branch with the highest value.

Q10. What does a high risk-premium imply for a project's MARR?

High-risk projects require a higher risk-premium, which increases the Minimum Attractive Rate of Return (MARR) used to discount its cash flows.

Frequently Asked / Viva Questions (contd.)

Q11. What is the purpose of Monte Carlo simulation in risk analysis?

It allows the engineer to model parameters as probability distributions rather than single-point estimates, generating a distribution of possible PW outcomes.

Q12. What are Real Options in engineering project management?

The managerial flexibility to adapt decisions in response to market changes, such as the option to expand, contract, defer, or abandon a project.

Comparison of Project Selection Methods under Equivalence

Method	Core Metric	Study Period Rule	Primary Application
Present Worth (PW)	Net present value at $t = 0$	Must be equal (use LCM for unequal lives)	Comparing mutually exclusive projects with defined lives.
Annual Worth (AW)	Equivalent uniform annual series	Equal to useful life (does not require LCM)	Comparing alternatives with unequal service lives easily.
IRR	Discount rate where $PW = 0$	Compare IRR to MARR; requires incremental analysis	Evaluating single projects or ranking capital budgets.
BCR	Ratio of discounted benefits to costs	Equal study period required	Public sector projects and government infrastructure.

Module 4

Depreciation Calculations

1. Depreciation Calculations

Assets lose value over time, which affects taxes and company value.

1.1 Depreciation Concepts

Depreciation: The systematic allocation of the cost of a tangible asset over its useful life to represent wear, tear, physical deterioration, or obsolescence.

Book Value (BV_t): The remaining value of an asset recorded in accounting books after subtracting accumulated depreciation from the initial cost.

1.2 Straight-Line (SL) Depreciation

The simplest method; allocates an equal amount of depreciation to each year of the asset's life.

Straight-Line Formulas

For initial cost C , salvage value S , and useful life n :

$$\text{Annual depreciation: } d_t = \frac{C - S}{n} \quad (31)$$

$$\text{Book value in year } t : BV_t = C - (t \times d_t) \quad (32)$$

1.3 Declining Balance (DB) & Double Declining Balance (DDB)

An accelerated method where depreciation is calculated as a fixed percentage of the remaining book value.

Declining Balance Formulas

The depreciation rate α is given by:

$$\alpha = \frac{\text{Factor}}{n} \quad (\text{For Double Declining Balance DDB, Factor} = 2) \quad (33)$$

Annual depreciation, book value, and accumulated depreciation calculations:

$$\text{Depreciation in year } t : d_t = \alpha \times BV_{t-1} \quad (34)$$

$$\text{Book value in year } t : BV_t = C \times (1 - \alpha)^t \quad (35)$$

Note: An asset cannot be depreciated below its salvage value. Once BV_t reaches S , depreciation stops.

2. Replacement Analysis

Replacement analysis determines when an existing asset should be replaced by a new one.

2.1 Economic Service Life (ESL)

The **Economic Service Life (ESL)** is the asset life k^* that minimizes the total equivalent annual cost. It is the optimum point that balances capital costs and rising operating costs.

Total Annual Cost Equation

The Total Annual Cost (ATC) of owning an asset for k years at interest rate i is:

$$ATC(k) = CR(k) + AEC_{O\&M}(k) \quad (36)$$

Where:

$$\text{Capital Recovery cost: } CR(k) = [C - S_k(P/F, i, k)] \times (A/P, i, k) \quad (37)$$

$$\text{Equivalent Annual O\&M: } AEC_{O\&M}(k) = \left[\sum_{t=1}^k O\&M_t \times (P/F, i, t) \right] \times (A/P, i, k) \quad (38)$$

2.2 Defender vs. Challenger Comparison

- **Defender (D):** The existing asset currently in use.
- **Challenger (C):** The best available replacement candidate.

Replacement Decision Process Flowchart

Marginal Cost of Defender next year:

$$MC_D(t+1) = (MV_t - MV_{t+1}) + (MV_t \times i) + O\&M_{t+1} \quad (39)$$

Where MV_t is current market value, MV_{t+1} is market value next year, and $O\&M_{t+1}$ is operating cost next year.

3. Basic Accounting for Engineers

Engineers must understand financial statements and cost allocation to make business decisions.

3.1 Financial Statements

1. **Balance Sheet:** Represents a snapshot of the firm's financial position at a specific point in time. It satisfies the fundamental accounting equation:

$$\text{Assets} = \text{Liabilities} + \text{Owner's Equity} \quad (40)$$

2. **Income Statement:** Summarizes revenues and expenses over a period of time (e.g., quarter or year) to calculate net income:

$$\text{Net Income} = \text{Revenues} - \text{Expenses} \quad (41)$$

3.2 Financial Ratios

- **Liquidity (Current Ratio):** $\text{Current Ratio} = \frac{\text{Current Assets}}{\text{Current Liabilities}}$
- **Profitability (Return on Equity):** $ROE = \frac{\text{Net Income}}{\text{Owner's Equity}}$
- **Leverage (Debt-to-Equity):** $\text{Debt-to-Equity} = \frac{\text{Total Liabilities}}{\text{Owner's Equity}}$

3.3 Cost Accounting and Allocation

- **Direct Costs:** Costs directly traceable to a product or service (e.g., direct materials, assembly labor).
- **Indirect Costs (Overhead):** Costs that cannot be easily traced to a specific product (e.g., building rent, supervisor salaries, factory electricity).
- **Indirect Cost Allocation:** Distributing overhead costs to products using allocation bases like direct labor hours, machine hours, or direct material costs.

4. Worked Examples

Example 1: Double Declining Balance (DDB)

Problem: A test instrument costs \$80,000, has a useful life of 5 years, and a salvage value of \$10,000. Calculate the depreciation amount and book value for Year 1 and Year 2 using the DDB method.

Solution: Identify parameters: Cost $C = \$80,000$, Life $n = 5$, Salvage value $S = \$10,000$. Calculate DDB rate α :

$$\alpha = \frac{2}{n} = \frac{2}{5} = 0.40 \quad (40\% \text{ per year})$$

• **Year 1:**

Depreciation: $d_1 = \alpha \times BV_0 = 0.40 \times 80,000 = \$32,000$

Book Value: $BV_1 = C - d_1 = 80,000 - 32,000 = \$48,000$

• **Year 2:**

Depreciation: $d_2 = \alpha \times BV_1 = 0.40 \times 48,000 = \$19,200$

Book Value: $BV_2 = BV_1 - d_2 = 48,000 - 19,200 = \$28,800$

Since $BV_2 = \$28,800 > S = \$10,000$, we do not need to adjust for the salvage value floor yet.

Answer: Year 1: Depreciation = \$32,000, Book Value = \$48,000. Year 2: Depreciation = \$19,200, Book Value = \$28,800.

Example 2: Replacement Analysis

Problem: An existing compressor (defender) has a current market value of \$5,000. If kept for another year, its market value will fall to \$3,500 and operating costs will be \$6,500. A new compressor (challenger) has a minimum annual cost of \$8,000. At an interest rate of 10%, should the company replace the compressor now?

Solution: Calculate the Marginal Cost of the defender (MC_D) for next year:

- Current market value $MV_t = \$5,000$, Market value next year $MV_{t+1} = \$3,500$.
- Interest rate $i = 0.10$.

- Operating and Maintenance cost $O\&M_{t+1} = \$6,500$.

$$\begin{aligned} MC_D &= (MV_t - MV_{t+1}) + (MV_t \times i) + O\&M_{t+1} \\ MC_D &= (5,000 - 3,500) + (5,000 \times 0.10) + 6,500 \\ MC_D &= 1,500 + 500 + 6,500 = \$8,500 \end{aligned}$$

Compare MC_D next year with the minimum annual cost of the challenger ($ATC_C^* = \$8,000$):

$$MC_D(\$8,500) > ATC_C^*(\$8,000) \quad (\text{Keeping defender is more expensive})$$

Since the marginal cost of keeping the defender exceeds the annual cost of the challenger, the defender should be replaced.

Answer: Replace now, as keeping the defender for another year costs \$8,500 compared to the challenger's annual cost of \$8,000.

Example 3: Indirect Cost Allocation

Problem: A workshop incurs factory overhead costs of \$12,000. It produces two products: Product A (requires 400 direct labor hours) and Product B (requires 800 direct labor hours). Allocate the overhead cost to both products using direct labor hours as the allocation base.

Solution: Identify parameters: Total Overhead = \$12,000, Total Labor Hours = 400 + 800 = 1,200 hours. Calculate the overhead allocation rate:

$$\text{Allocation Rate} = \frac{\text{Total Overhead}}{\text{Total Labor Hours}} = \frac{12,000}{1,200} = \$10 \text{ per labor hour}$$

Allocate overhead to each product:

- **Product A:**

$$\text{Allocated Overhead} = 400 \text{ hours} \times \$10/\text{hour} = \$4,000$$

- **Product B:**

$$\text{Allocated Overhead} = 800 \text{ hours} \times \$10/\text{hour} = \$8,000$$

Verification: $\$4,000 + \$8,000 = \$12,000$ (total overhead allocated).

Answer: Product A is allocated **\$4,000** and **Product B** is allocated **\$8,000**.

Quick Revision — Module IV

Depreciation, Replacement & Accounting | HS-HU601

Key Formulas at a Glance

Straight-Line Dep.	$d_t = \frac{C - S}{n} \quad (BV_t = C - t \times d_t)$
Declining Balance Dep.	$d_t = \alpha \times BV_{t-1} \quad (BV_t = C \times (1 - \alpha)^t)$
DDB Rate	$\alpha = \frac{2}{n}$
Capital Recovery	$CR(k) = [C - S_k(P/F, i, k)] \times (A/P, i, k)$
Defender Marginal Cost	$MC_D(t+1) = (MV_t - MV_{t+1}) + (MV_t \times i) + O\&M_{t+1}$
Accounting Equation	Assets = Liabilities + Owner's Equity
Current Ratio	Current Ratio = $\frac{\text{Current Assets}}{\text{Current Liabilities}}$

One-Line Definitions

- **Depreciation:** Allocation of an asset's cost over its life to account for wear and tear.
- **Book Value:** Cost of an asset minus accumulated depreciation.
- **Economic Service Life:** The asset life that minimizes total equivalent annual cost.
- **Defender:** An existing asset currently owned and operating.
- **Challenger:** The best replacement candidate available.
- **Balance Sheet:** Statement showing assets, liabilities, and equity at a specific point in time.
- **Income Statement:** Statement showing revenues, expenses, and net profit over a period.
- **Direct Cost:** Expense directly traceable to a product (e.g., labor, raw materials).
- **Indirect Cost:** Expense that cannot be easily traced to a product (e.g., rent, utilities).

Frequently Asked / Viva Questions

Q1. What is the difference between physical deterioration and obsolescence?

Physical deterioration is wear and tear due to usage or environmental factors. Obsolescence is the loss of value due to technological progress (newer, better alternatives).

Q2. Explain the Straight-Line depreciation method.

It allocates an equal amount of depreciation to each year of the asset's useful life:

$$d_t = (C - S)/n.$$

Q3. What is the salvage value floor rule in Declining Balance methods?

An asset cannot be depreciated below its salvage value. Once the book value (BV_t) drops to the salvage value (S), depreciation must stop.

Q4. Define the Economic Service Life (ESL) of an asset.

The period of ownership that minimizes the sum of equivalent annual capital recovery costs and annual operating and maintenance costs.

Q5. What costs are included in the Capital Recovery cost (CR) of an asset?

The annualized cost of depreciation (loss in asset value) and the interest cost on the capital invested in the asset.

Q6. How is the defender's marginal cost for next year calculated?

By adding the projected loss in market value, the interest on its current market value, and the operating and maintenance costs for next year.

Q7. State the decision rule in Defender vs. Challenger replacement analysis.

If the marginal cost of keeping the defender for one more year is greater than the minimum annual cost of the challenger, replace the defender immediately.

Q8. State the fundamental accounting equation.

Assets = Liabilities + Owner's Equity. It forms the basis of the Balance Sheet.

Q9. What is the difference between direct and indirect costs in manufacturing?

Direct costs can be traced directly to a product (e.g., material). Indirect costs cannot be traced directly and must be allocated (e.g., factory rent).

Q10. What is the Current Ratio, and what does it measure?

Current Assets divided by Current Liabilities. It measures a firm's liquidity (ability to pay off short-term debts).

Frequently Asked / Viva Questions (contd.)

Q11. Explain the concept of overhead cost allocation.

The process of distributing indirect costs (like supervisor salaries or utilities) to different products using an allocation base like direct labor hours.

Q12. What is the Double Declining Balance (DDB) depreciation rate?

It is twice the straight-line rate: $\alpha = 2/n$. It represents accelerated depreciation in the early years of asset ownership.

Comparison of Depreciation Methods

Method	Depreciation Pattern	Calculation Base	Primary Use
Straight-Line	Constant annual depreciation	$(C - S)$ is constant	Standard accounting; simple financial reporting.
Declining Balance	Accelerated; higher in early years	Remaining book value (BV_{t-1})	Assets that lose value quickly (vehicles, computers).
Double Declining	Maximum acceleration rate ($2/n$)	Remaining book value (BV_{t-1})	Tax reporting (maximizes early tax shields).
Sinking Fund	Increases over time	$(C - S)$ with interest	Special asset funds; rarely used in modern tax accounting.
